Project Title:
Script-Controlled ACL – Restrict Record Access Based on Field Value

3. Project Design Phase

The project design defines how ServiceNow Access Control Lists (ACLs) will control access to records in the **u_institution_details** table. The design uses role-based access and a Branch field condition as the main security components.

The Read ACL is designed for the **u_institution_details** table with the operation set to Read and Advanced enabled. The ACL requires the **bb1** role and uses the data condition **Branch is EEE**. The script is designed to allow administrators full access and to allow users having the required **bb1** role, while denying access to users who do not satisfy the access requirements.

Separate ACLs are designed for the remaining operations. The **Create ACL** requires the **bb2** role, the **Write ACL** requires the **bb3** role, and the **Delete ACL** requires the **bb4** role. These ACLs are configured for the same **u_institution_details** table and are designed without an additional data condition.

The Institution Details table is designed with fields including Student Roll Number, Student Name, Faculty Name, Branch, Email, Phone Number, and Description. The **Branch** field contains the choices **ECE, EEE, and CSE** so that record access can be controlled according to the required branch condition.

The overall design ensures that users are assigned the required combination of roles for the operations they need. The intended access flow is that users with **bb1** can access permitted EEE records, **bb2** provides Create access, **bb3** provides Write access, and **bb4** provides Delete access, while administrators retain full access.
